The project we have been assigned is called *PowerEnjoy* and it is a complex software system that should implement a car sharing service. In order to rationalize, clarify, and put in structured and standardized documents all the relevant concepts and informations, we designed and delivered several documents such as the **RASD**, the **DD**, the **ITPD**, and the **PPD**. These slides will only present an overview of the concepts thoroughly described in the above mentioned documents.

We composed the documents we had to using some tools such as:

- **TexStudio:** to compile \LaTeX document.
- **StarUML:** to draw UML diagrams.
- **Alloy Analyzer 4.2:** to checking model consistency.
- **Draw.io:** to build mockups.
- **GitHub:** for storing the project.
- **Skype:** for team collaboration

The aim of the software is to provide a new digital management system for car-sharing service that exclusively uses electrical cars. It can be applied to different small and big city and even in a large urban area.

This new service pretends to achieve various goals, such as:

- **G4:** Allow user logged in to book a car in a certain location.
- **G6:** A user who request a rent can abort the process whenever he/she wants.
- **G9:** A non registered users can only register once to the service.
- **G10:** A user can get discount or overtaxes from his/her last rent.

Below are listed the four main actors that will interact with the application once deployed:

- **Registered User:** A person who subscribed to the system and can access to all functionalities of the application.
- **Visitors:** A person that needs to move from a position to another one among the city and wants to use *PowerEnJoy* in order to do so, but has not registered yet to the service.
- **Car:** The car reserved / rented / Parked that communicates with the system.
- **External Customer Service:** A team that provide technical support in case of problems related to the car.

Our *PowerEnJoy* is a **completely new product**, not based on previous ones.

It relies on **location data** received via **Internet** from each user application and car system: all the involved smartphones already have a **GPS antenna** installed inside, that communicates their position to the service.

Being a partially **distributed application**, *PowerEnJoy* requires a fully operative **Internet** connection in order to work properly, both on server and client side: **no service is intended to be provided offline**.

All the data generated by this software are stored in a database, accordingly to current normative and laws about privacy and personal data management.

In addition, several **APIs** are provided in order to allow further improvements and expansions of the software: for instance, the payment will be managed from an external entity (we supposed **PayPal**) and the map will be provided by **Google**.

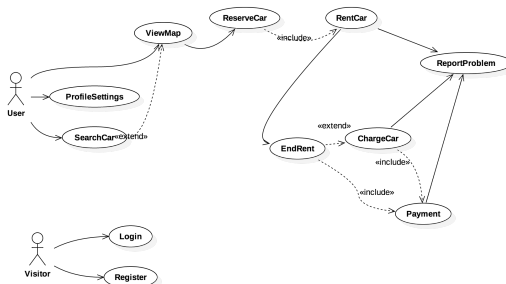

Tasks Scheduling

We provided a variety of UML diagrams, each type having a different purpose.

- UML Use Case
- UML Sequence Diagram
- UML Class diagram

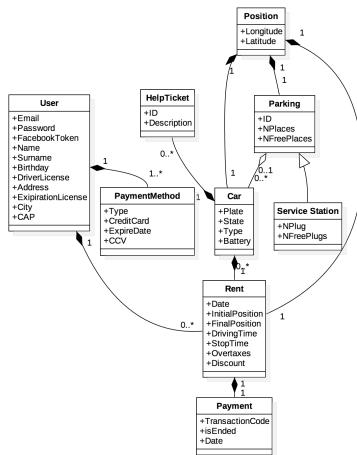

UML Use Case Diagram

This is perhaps the most useful diagram that can be designed in the early phase of the development of a software project.

UML Class Diagram

Furthermore we designed a class diagram for an early evaluation of the basic software components that consists in a sort of **Model** for *PowerEnJoy*.

Alongside the **UML Class Diagram** we built **Alloy Models** using the **Alloy** modeling language with the help of **Alloy Analyzer 4.2**.

The tool didn't find a proof of the inconsistency of our **Alloy Models**, and that along with the **Automatic Generation** (and **Manual Verification**) of interesting worlds, made us aware of the **Consistency** of those **Models** within a reasonable level of confidence.

Alloy Simple World

Here is an example of one among the **simplest world** we generated and double checked using both **Alloy Analyzer 4.2** and **manual checking**.

- The **Client-Server** style is used to give the many Clients connected to the Server the opportunity of sending different requests (e.g. a **Car Reservation** or **Open Car Request**).
- The **Point to Point** bidirectional communication channel is made necessary to enable the Server the delivery of various messages and requests to the Clients and the Car:
 - Generic notifications
 - Service messages
 - Internal message to the car as Open or Check the status

The selected software architecture follows the principles of the **Model View Controller** architectural pattern, therefore three main software components have been identified and those are:

- The **View**, the user application View that is designed to perform comfortable user experience

- The **Controller**, in charge of leading the communication between views and process either **synchronous responses** or **asynchronous events**.
- The **Model** that guarantees a high level interface to store and manage all the *PowerEnJoy* relevant data and an abstraction of **Relational Database** in a software component that is in direct connection with the **Controller**

The selected software architecture follows the principles of the **3-Tiers** architecture. Therefore our structure expands this concept by adding 1 additional tiers to interact with the external world

In particular the tiers are:

- The **Client**, the mobile application designed and projected
- The **Application Server**, the main core of the system that include **Controller** and **Model** into it
- The **DB Server**, the data storage of the *PowerEnJoy*' data.
- The **Car System**, that is the interface between the physical system and the software, furnished by sensor and display in order to communicate with the user.

The best way found to deploy the software components identified, is to consider 4 different nodes (7 if considering the Google Server and the PayPal server) that correspond with the **Tiers** with in addition the **External Extentions**

Deployment View - UML

Deployment Diagram

The following diagram shows how **software components** are mapped into the **physical system**.

Here are proposed some of the most meaningful **UML Sequence Diagrams** with respect to show how software components interacts. The chosen functionalities are:

- Find a FreeCar
- Make a Reservation

There are other functionalities whose **UML Sequence Diagram** is not reported here for space and time constraints:

Find a FreeCar

Scope and Approach

This project phase is highly based on the **Design** one.

We will clearly state the order in which the software components identified in the **Component View** of the **Design** part have to be integrated one with each other in order to guarantee a well tested final software.

The **bottom-up integration testing approach** has been chosen, because for a medium sized project like *PowerEnjoy*, it is best to proceed step by step in a careful yet coherent integration strategy.

Before starting the integration testing of any software component that has been designed for *PowerEnJoy* system, few points have to be underlined:

- The **internal functions** of the considered component must be **unit tested** using an appropriate framework.
- We suppose that **Google Maps API and PayPal API** are well tested by **Google and PayPal** and thus we can use them without testing any further.

We have considered all the **Subsystems**. and we had divided into 3 different categories, in particular we divided the system in part based on the drivers' number. Trying to minimize the number of drivers to use in a **bottom-up** strategy.

- **Green:** This block is not dependent on any lower level component in *PowerEnJoy* and therefore it is integrated as a starting point in the current diagram.
- **Red:** This block is going to use some Drivers in order to perform a complete test on all its functionalities
- **Yellow:** This block is going to be tested without Drivers because it's at the end of the process.
- **Blue:** This block will be not tested.

Program Drivers And Data Required

In conclusion there is the need for some sample data to be in the **Database** and some sample **GPS data** are needed.

Tasks Scheduling

Tasks Scheduling

In order to estimate the project effort, we followed the assumption that the **dimension of the software** can be characterized by correlating **the kind of functionalities offered** with **the source lines of code (SLOC) of the software itself**

The **Function Points approach**, defined in 1975 by Allan Albrecht:

- Consists in a technique to assess the effort needed to design and develop custom software applications.
- Correlates the kind of functionalities offered with the source lines of code of the software itself.

This technique consists in combining the following program characteristics to obtain a final result:

- Internal Logic Files
- External Logic Files
- External Input
- External Output
- External Inquiry

All the calculated FP_i sums up to FP , which is the total Function Points value:

$$\begin{aligned} FP &= FP_{ILF} + FP_{ELF} + FP_{EI} + FP_{EO} + FP_{EIQ} \\ &= 80 + 10 + 35 + 16 + 8 \\ &= 149 \end{aligned}$$
